

More Classical Software Architectures: N-Tier, Client-Server, Peer-to-Peer, and MVC

Dr. Riad Sonbol

Course Roadmap

- General Principles in Software Design and Architecture: *The Context of Software Architecture, System Decomposition, What is Good Design?*
- Layered Architecture
- Practical Concerns 1: Communication between Layers, Façade Design Pattern, and Dependency Injection
- N-Tier, Client-server, Peer-to-Peer, MVC
- Microservices
- Practical Concerns 2: Message Broker, Related Design Patterns: CQRS, API Gateway, Strangler Pattern, Externalized Configuration, case study
- Clean Architecture: The Hexagonal Architecture, Ports and Adapters
- More Architectural Styles: Repository, Service-Oriented Architecture (SOA), Pipes and Filters

More Classical Software Architectures: N-Tier

3-Tier architecture

- **Layers** are **logical** separation of related-functional code within the application.
- **Tiers** are **Physical** separation of layers which get hosted on Individual servers in an individual computer(process).
- n-Tier advantages:
 - Better Security
 - Scalability : e.g. You can scale up your DB-Tier with DB-Clustering if needed.
 - Maintainability
 - Easily Upgrade or Enhance

3-Tier architecture

- **Presentation tier:**

- Focus on user interface concerns: Logic to render the user interface, including the placement of data, formatting the data, and hiding/showing UI components as required
- Basic validation.

- **Business tier:**

- Provides the implementation for the BL of the application: Business rules, validations, and calculation logic, Business entities for the application's domain.
- serves as an intermediary between the presentation and data tiers.

- **Data tier:** The data tier provides functionality to access and manage data.

More Classical Software Architectures: Client-Server

Client-server architecture (2-tier architecture)

- In a distributed application that uses a client-server architecture, also known as a two-tier architecture, clients and servers communicate with each other directly.
- A client requests some resource or calls some service provided by a server and the server responds to the requests of clients.
- There can be multiple clients connected to a single server.

contains the user interface code

Contains the relational database management system (RDBMS)

The majority of application logic

Client-server architecture (2-tier architecture)

- When the client contains a significant portion of the logic and is handling a large share of the workload, it is known as a thick, or fat, client. When the server is doing that instead, the client is known as a thin client.

a) Thick client architecture

b) Thin client architecture

More Classical Software Architectures: P2P

Peer-to-Peer Architectural Style

- A generalization of the client/server architectural style.
- Each subsystems can act as client or as servers, in the sense that each subsystem can request and provide services.
- Sample Applications?
 - Easy file sharing.
 - Efficient instant messaging.
 - Smooth voice communication.

Architecture	Description	Advantages	Disadvantages	Sample Usage
Layered Architecture	Organized into layers where each layer performs a specific role (e.g., presentation, business logic, data access)	- Modular and promotes separation of concerns - Easy to develop, test, and maintain - Supports reusability	- Can lead to performance overhead due to multiple layers - May increase latency in layer communication	Web applications, enterprise software
Client-Server	Divides the system into client and server, where clients request services, and servers provide them	- Centralized control and management - Easy to secure and monitor - Scales well for small to medium systems	- Server can become a bottleneck in high load - Can lead to single point of failure without redundancy	Email systems, online games
n-Tier	Extends client-server with additional layers (e.g., presentation, application, and data tiers)	- Highly scalable and flexible - Separates functionality into distinct services - Easy to distribute layers	- Complex to implement - Higher latency as requests go through multiple layers	E-commerce platforms, Banking systems
Peer-to-Peer (P2P)	Each node (peer) in the network can act as both client and server, sharing resources directly	- Decentralized, no single point of failure - Efficient resource sharing - Scalable without central server	- Difficult to secure and manage - Complex to maintain consistency across peers	File sharing networks, blockchain, VoIP

MVC Architecture

Model-View-Controller

- Model–view–controller (MVC) is a software architecture pattern which separates the representation of information from the user's interaction with it.
- A Model View Controller pattern is made up of the following three parts:
 - Model
 - View
 - Controller

Model-View-Controller

*Being “architectural”,
these components
may contain many
subcomponents
(classes, etc.)*

Model-View-Controller

Remember:

Component = clear Responsibilities

“Responsibility-Driven Design”

- ✓ *How to assign responsibilities to objects*
- ✓ *How objects should collaborate*
 - ✓ *What role each object should play in a collaboration*

Single responsibility principle

Every object in your system should have a **single responsibility**, and all the object's services should be focused on carrying out that single responsibility.

Responsibilities

Responsibilities: View

- The View **displays** the data.
- The View **knows about the Model**. It will poll the Model about the state, **to know what to display**.
- The View **knows nothing about the Controller**.

Responsibilities: Model

- The model is responsible for **managing and maintaining the data** of the application.
- The Model represents the **application core** (for instance a list of database records).
- It is also called the “domain layer”
- The Model **knows only about itself**.
- That is, the source code of the Model has no references to either the View or Controller.

Respo...:Controller

- The Controller is the part of the application that **handles user interaction**.
- Typically controllers **read data from a view, control user input, and send input data to the model**.
- It **handles the input**, typically user actions and may **invoke changes** on the model and view.
- The Controller **knows about both** the Model and the View.

Router

Workflow in MVC - Example

The control flow generally works as follows:

1. The user interacts with the user interface in some way (e.g., **user presses a button**)
2. A controller handles the input event from the user interface, often via a **registered handler or callback**.
3. The controller accesses the model, possibly updating it in a way appropriate to the user's action (e.g., **controller updates user's shopping cart**).
4. A view uses the model to generate an appropriate user interface (e.g., **view produces a screen listing the shopping cart contents**).

The view gets its own data from the model. The model has no direct knowledge of the view.

Advantages

- Clear separation between presentation logic and business logic.
 - No matter how the View class is modified, the Model will still work.
 - Even if the system is moved from a desktop operating system to a smart phone, the Model can be moved with no changes.
 - But the View probably needs to be updated, as will the Controller.
- The MVC programming model is a lighter alternative to traditional Web Page/Forms.
- It is a lightweight, highly testable framework, integrated with all existing features, such as Security, and Authentication.
- parallel development
- easy to maintain and future enhancements

Example: Model

```
public class User {  
    private String name;  
    private String email;  
  
    public User(String name, String email) {  
        this.name = name;  
        this.email = email;  
    }  
  
    // Getters and setters  
    public String getName() { return name; }  
    public void setName(String name) { this.name = name; }  
  
    public String getEmail() { return email; }  
    public void setEmail(String email) { this.email = email; }  
}
```

Example: View

```
public class UserView {  
    public void printUserDetails(String userName, String userEmail) {  
        System.out.println("User Details:");  
        System.out.println("Name: " + userName);  
        System.out.println("Email: " + userEmail);  
    }  
}
```

Example: Controller

```
public class UserController {  
    private User model;  
    private UserView view;  
  
    public UserController(User model, UserView view) {  
        this.model = model;  
        this.view = view;  
    }  
  
    // Update model  
    public void setUsername(String name) { model.setName(name); }  
    public void setUserEmail(String email) { model.setEmail(email); }  
  
    // Retrieve model data  
    public String getUsername() { return model.getName(); }  
    public String getUserEmail() { return model.getEmail(); }  
  
    // Update view  
    public void updateView() {  
        view.printUserDetails(model.getName(), model.getEmail());  
    }  
}
```

Example

```
public static void main(String[] args) {  
    // Create Model  
    User user = new User("Alice", "alice@example.com");  
  
    // Create View  
    UserView view = new UserView();  
  
    // Create Controller  
    UserController controller = new UserController(user, view);  
  
    // Display initial details  
    controller.updateView();  
  
    // Update model via controller  
    controller.setUserName("Alice Smith");  
    controller.setUserEmail("alice.smith@example.com");  
  
    // Refresh view  
    controller.updateView();  
}
```

Where should you place your **business logic**!

- The placement of business logic largely depends on the **complexity** and **scope** of that logic.

Where should you place your **business logic**!

(1) Small or Simple Business Logic

- If the business logic is relatively simple (e.g., validating input data, basic calculations, or fetching filtered data),

Where should you place your **business logic**!

(2) Medium Complexity Business Logic

- If the business logic involves multiple models or complex workflows (e.g., handling orders, applying discounts, or processing payments).
- You should **avoid** placing it directly in Controllers or Models to keep your code maintainable.
- **Solution!**

Where should you place your **business logic**!

(2) Medium Complexity Business Logic

- (A) Create a separate **services module** for handling these operations.
- dedicated Service Layer helps to decouple business logic from Controllers and Models, making it easier to test and maintain.

The Controller would then use this service!

```
class OrderService:
    def calculate_discounted_total(order):
        total = sum(item.price for item in order.items)
        return total * 0.9 if order.is_eligible_for_discount() else total
```

```
class OrderController:
    def show_order_summary(self, order_id):
        order = OrderModel.get_order_by_id(order_id)
        total = OrderService.calculate_discounted_total(order)
        return render_view('order_summary', {'total': total})
```

Where should you place your **business logic**!

(2) Medium Complexity Business Logic

- (B) Treat the **Model as a Domain Entity or Business Object (BO)** that encapsulates business logic related to the data stored in the database.
- **Models as Domain Entities/BOs** are best when the logic is **data-centric** and directly related to the entity itself.
- However, if the business logic is more complex or involves **cross-cutting concerns** (like external service integrations, multiple models, or workflows that span different entities), it's better to use a **Service Layer**.

Where should you place your **business logic**!

(3) Heavy or Long-Running Business Logic

- For complex operations that are **computationally intensive** or need to be executed **asynchronously** (e.g., generating reports, batch processing, or sending emails) it's best to **decouple them from the request/response cycle**.
- Offloading heavy processing to **background workers** improves performance and scalability.

MVC Variations

MVC	MVT
Controller	View
Model	Model
View	Template

Django MVT Architecture

•The **View** executes the business logic and interacts with the Model and renders the template. It accepts HTTP request and then return HTTP response.

•Templates act as the presentation layer and are basically the HTML code that renders the data. The content in these files can be either static or dynamic.

حالة عملية للنقاش

شركة تطوير تعمل على بناء نظام برمجي لإدارة خدمات الرعاية الصحية عن بُعد، ويتميز النظام المراد بالخصائص التالية:

- يتكامل النظام مع أجهزة قياس العلامات الحيوية للمرضى لتحصيل البيانات والقياسات الحيوية مباشرة لتحليلها.
- يوفر واجهة مستخدم تفاعلية للأطباء والمرضى تتيح لهم مراقبة الحالة الصحية للمرضى بشكل لحظي عند الحاجة وتقديم الاستشارات عبر الإنترنت.
- يتيح النظام للمرضى حجز المواعيد والتواصل مع الأطباء عبر المحادثات النصية أو مكالمات الفيديو.
- يقدم النظام توصيات طبية مخصصة بناءً على بيانات المرضى وسجلهم الصحي باستخدام تقنيات الذكاء الاصطناعي.
- يوفر النظام خدمة إدارة الوصفات الطبية الإلكترونية، حيث يمكن للأطباء إصدار الوصفات وتحويلها مباشرة إلى الصيدليات.
- يدعم النظام تخزين الملفات الطبية بشكل آمن مع إمكانية مشاركتها مع مقدمي الرعاية الصحية بناءً على موافقة المريض.
